Should wood stove combustion air retrofits be improved?

The admission of secondary air allowed a 38%-42% reduction in the gaseous emissions. Wood stove combustion air retrofits should be improved to reduce PM 2.5 emissions. 1. Introduction Fireplaces and conventional wood stoves (WSs) continue to be used as reliable and renewable heating systems in Europe and other cold and temperate climate zones.

What is the thermal efficiency of a wood stove?

The thermal efficiency of the wood stove was 79% when using an annular chimney. The pellet stove reached a efficiency of 88% and a PM 2.5 emission of 0.7g kg F-1. The pellet and retrofitted wood stove generated a stable heat release (5-6kW). The admission of secondary air allowed a 38%-42% reduction in the gaseous emissions.

Can a wood stove improve energy performance?

This investigation showed that the energy performance of wood stoves in dwellings can substantially be increased at a relatively low cost by using alternative combustion air admission components operated at natural draft.

Is direct combustion of waste oil better than other fuel/stove combinations?

Direct combustion of waste oil in stove can be a better choice than other fuel/stove combinations when comprehensively considering fuel conservation, energy cost, air pollution and human health impacts (Table 4).

Can waste oil be used as a fuel for a stove?

Rate the emission of stove fueled with waste oil by current available standards. Direct use of waste oil as fuel to meet the residential energy demands, is very attractive due to its potentials to decrease fossil fuel consumption, reduce pollution and increase sustainability.
