How do nanostructures store and dissipate electromagnetic energy?

The processes of storage and dissipation of electromagnetic energy in nanostructures depend on both the material properties and the geometry. In this paper, the distributions of local energy density and power dissipation in nanogratings are investigated using the rigorous coupled-wave analysis.

Is power dissipation related to energy storage?

Both power dissipation and energy storage are related, since electric and magnetic fields can store energy. However, for nonmagnetic materials, only electric current can result in power dissipation. Understanding this relationship may offer deep insight into the radiative properties of nanostructures.

Do nanogratings have local energy storage and power dissipation density?

The local energy storage and power dissipation density in the nanogratings are investigated using the RCWA method. This information helps to understand the geometric effect on the global radiative properties of nanogratings.

Do materials optical properties affect energy storage and power dissipation density?

The optical property of materials has been studied by many researchers in relation to energy storage and power dissipation density. Early works on this topic were conducted by Loudon, Barash, Ginzburg, Brillouin, and Landau, among others. More recent studies have been carried out by Ruppin, Shin et al., and Vorobyev.

Does energy storage enhance absorption?

The enhancement of absorption is accompanied by the improvement of energy storage for material at the resonance of its dielectric function, described by a classical Lorentz oscillator model, and for nanostructures at the resonance induced by the geometric structure.

What is a dimensionless total energy storage?

For the convenience of analysis, a dimensionless total energy storage  $U_{\text{total}}$  is defined as  $U_{\text{total}} = U / (u_0 V)$ , where  $V$  denotes the volume of the grating layer.

In superconducting magnetic energy storage (SMES), energy is stored or extracted from the magnetic field of an inductor, by decreasing the current in the windings of the coil. These magnetic devices can be discharged quite instantaneously, delivering high power output.

The harvesting energy from vibrating environments can be stored by batteries to supply low-power devices. This paper presents a new structure of magnetic levitation energy harvester (MLEH) for low-power-device's energy storage, which uses magnetic liquid to improve energy conversion efficiency and broaden bandwidth.

The first is the energy storage stage when the mechanical energy of the PM is converted into magnetic energy stored in the two HTS coils. In this process, controlling the mechanical drive to move the PM from the initial position A into the two HTS coils.

CoFe<sub>2</sub>O<sub>4</sub>, a typical spinel-type ferrite, is commonly employed in electromagnetic wave absorber applications, owing to its notable saturation magnetization strength, significant anisotropy, and excellent chemical stability characteristics [10], [11]. Nevertheless, the high density of pure CoFe<sub>2</sub>O<sub>4</sub> renders the matching impedance inadequate in real-world applications, ...

The charging process took 240 s. Under ideal conditions, the outputs of the piezoelectric energy harvester and the electromagnetic energy harvester were connected to unidirectional bridge rectifiers (MDQs), respectively, which were then connected in parallel with a 1000 mF capacitor for charging.

Maximum output average powers of up to 1.79 W and 1.39 W were measured for the system with 4 or 2 active coils, respectively, at an optimal load of 30 kΩ under resonance conditions at 18 Hz. The resonant peak values increase with the input amplitude essentially due to the optimal loads being closer to the internal resistances in Eq. (28).

Figure 2 presents energy harvesting comparison of the BEEH with the resonant circuit and that with a pure resistor ( $R = 500 \Omega$ ), where the electrical governing equation of the resonant circuit is defined by Eq. (1). The result shows that the displacement of the BEEH is almost the same with the resonant circuit and pure resistor circuits when  $f_r$  is 4.24.

The frequency bandwidth is very important for improving the applicability of energy harvester, which motivates many scholars to carry out structural exploration of magnetic levitation energy harvester [31], [32].
