#### What is the rate of energy storage in a Magnetic Inductor?

Thus, the power delivered to the inductor p = v \*i is also zero, which means that the rate of energy storage is zero as well. Therefore, the energy is only stored inside the inductor before its current reaches its maximum steady-state value, Im. After the current becomes constant, the energy within the magnetic becomes constant as well.

#### How does an inductor work?

The inductor behaves like a load and stores energy to prevent ripples from producing excess current. It acts like a current supply when the ripple reduces the current value. In each case, the inductor prevents the ripples from influencing the regulated DC.

### What happens when an excited inductor loses connection to the supply?

When an excited inductor loses connection to the supply, it quickly breaks its magnetic fields and tries to continue the connection to the supply with the converted energy. This energy can cause destructive arcing around the point where the connection is lost. Thus, the connectivity of the circuit must be continuously observed.

### What happens when an inductive circuit is completed?

When an inductive circuit is completed, the inductor begins storing energy in its magnetic fields. When the same circuit is broken, the energy in the magnetic field is quickly reconverted into electrical energy. This electrical energy appears as a high voltage around the circuit breakpoint, causing shock and arcs.

What are some common hazards related to the energy stored in inductors?

Some common hazards related to the energy stored in inductors are as follows: When an inductive circuit is completed, the inductor begins storing energy in its magnetic fields. When the same circuit is broken, the energy in the magnetic field is quickly reconverted into electrical energy.

### How does a SMPS inductor work?

The inductor subdues any output current fluctuations by changing its behavior between a load and a supply based on the SMPS current ripple. The inductor behaves like a load and stores energy to prevent ripples from producing excess current. It acts like a current supply when the ripple reduces the current value.
