How do you calculate the energy stored in a capacitor?

Think of the capacitor as a triangle with one 90 deg angle: one side of that angle is the charge and the other side is the voltage. The area is the energy,  $E = 0.5 * Q * U$ ,  $Q = U * C$  Total Energy stored in the capacitor,  $= QV/2 = 0.5 CV^2$  where,  $Q$  = amount of charge stored when the whole battery voltage appears across the capacitor.

How do you calculate energy stored in a battery?

The area is the energy,  $E = 0.5 * Q * U$ ,  $Q = U * C$  Total Energy stored in the capacitor,  $= QV/2 = 0.5 CV^2$  where,  $Q$  = amount of charge stored when the whole battery voltage appears across the capacitor.  $V$  = voltage on the capacitor proportional to the charge. Then, energy stored in the battery  $= QV$

How to calculate capacitance of a capacitor?

The following formulas and equations can be used to calculate the capacitance and related quantities of different shapes of capacitors as follow. The capacitance is the amount of charge stored in a capacitor per volt of potential between its plates. Capacitance can be calculated when charge  $Q$  & voltage  $V$  of the capacitor are known:

What is the energy stored in a capacitor?

The energy stored in a capacitor is the electric potential energy and is related to the voltage and charge on the capacitor. If the capacitance of a conductor is  $C$ , then it is initially uncharged and it acquires a potential difference  $V$  when connected to a battery. If  $q$  is the charge on the plate at that time, then

How do you calculate the energy needed to charge a capacitor?

The total work  $W$  needed to charge a capacitor is the electrical potential energy  $UC$  stored in it, or  $UC = W$ . When the charge is expressed in coulombs, potential is expressed in volts, and the capacitance is expressed in farads, this relation gives the energy in joules.

What is an equivalent capacitance to a battery?

This logically suggests that when you talk about an "equivalent capacitance" to a battery that you mean a capacitor that stores or can deliver the same energy as the example battery. In theoretical terms your calculation is correct for an idealised battery (constant voltage throughout discharge, defined mAh capacity) and an idealised capacitor.

Capacity retention refers to the ability of a battery or a capacitor to retain the stored energy during an extended open-circuit rest time. The capacity retention of a cell is dependent on several factors, such as the rest time, the temperature of the cell during the rest period, and the cell's previous discharge and charge history.
