

How to store energy in a spring?

Energy can be stored in a Spring by winding it up in a clock-work device. When the winded spring is released in a controlled manner, it can be used for driving a dynamo which in turn generates electricity on rotation. However, one has to keep it in mind that it is appropriate only for low power application and for a limited duration.

How does a wind-up clock work?

A wind-up clock works by inputting energy rotationally with the input 'key'. This stored energy is then released rotationally to drive the clock's hands. Both a torsion bar and a 'coil' spring can be used to store this energy.

How did clockwork work?

Clockwork mechanisms relied on windup power instead of electricity. They used gears and springs to store and release energy, driving the movement of the device. This technology has stood the test of time, with the earliest known clockwork device, the Antikythera mechanism, dating back to ancient Greece over 2000 years ago.

What powers a mechanical clock?

Mechanical clocks are powered by energy stored in a wound spring or descending weights. Unlike modern battery-operated clocks, mechanical clocks rely on intricate mechanisms for their operation.

How long do windup clocks last?

Windup clocks and watches are designed to have springs that will store enough energy to keep the mechanism working for a day or more.

What does a clockwork machine do?

A clockwork machine uses a mechanism driven by gears to perform useful or interesting tasks. The gears control the speed and force of the machine, allowing it to do things like climb inclines. The gears are powered by a spring that releases its energy through them.

Yes, you got it. Chemical energy is converted to kinetic by the human body which is used to turn the wind-up mechanism. This kinetic energy is stored as potential energy by coiling a spring mechanism. When the spring is released, the stored potential is released as kinetic energy driving a dynamo generator producing electrical energy. The electrical energy provides ...

You will need a good clockwork spring to power your motor. These springs are made of steel and essentially are just long and narrow rectangle steel sheets. Such springs would be available in some local hardware stores.

When a clockwork radio is wound up, potential energy is stored in a spring or series of springs within the radio's mechanism. This stored mechanical energy serves as the primary source of power for the radio.. When the radio is switched on, the stored potential energy in the springs is gradually released, causing the spring to unwind.As the spring unwinds, it drives gears or ...

Also, do you think the last conversion in this step would be to electrical energy; you don't store it until step (iii). For part (v), this is basically correct, but have a think about how the sound energy is actually produced. Last edited: Dec 10, 2008. Dec 10, 2008 #5 dukg08. 12 0.

Theory. A clockwork radio is a radio device that gets its energy to produce sound through the potential energy stored in the spring that is inside it.. The more compressed the string is, the more potential energy it stores, and the radio can work longer. The fundamental issue is energy density. A spring simply doesn't store that much energy per unit mass and is ultimately limited by the yield stress of the material. Where springs are good is in providing large forces over a fairly short range of movement and time so they are good for things which require a fast response.
