

How is the energy stored in an inductor calculated?

The energy stored in the magnetic field of an inductor can be written as $E = 0.5 \cdot L \cdot I^2$, where L is the inductance and I is the current flowing through the inductor.

What happens when a voltage is applied to an inductor?

When a voltage is applied to the inductor, it causes the current to change, storing energy in the magnetic field. Conversely, when the voltage across the inductor is reversed, the energy stored in the magnetic field is released, changing the current in the opposite direction.

How can a volt-second balance be maintained in a power inductor?

By forcing a zero algebraic variation of the volt-second product, all solutions can keep the volt-second balance of the power inductor so that no risk of magnetic saturation in the transient state exists. The possibility of temporal overshoot current can be checked by verifying the monotonicity of the intermediate volt-second product.

How does a solar energy storage inductor work?

In this topology, the energy storage inductor is charged from two different directions which generates output AC current. This topology with two additional switching devices compared to topologies with four switching devices makes the grounding of both the grid and PV modules. Fig. 12.

How does an inductor store energy?

An inductor stores energy in its magnetic field. As the current through the inductor increases, it forces the magnetic lines of force to expand against their natural tendency to shorten. This expansion stores energy in the magnetic field, similar to how a rubber band stores energy when stretched.

What happens when an inductor reaches a steady-state value?

When the current in a practical inductor reaches its steady-state value of $I_m = E/R$, the energy stored by the inductor stops increasing. The magnetic field ceases to expand, the voltage across the inductance drops to zero, and the power becomes zero.

Again, no energy is dissipated by the inductor during the complete period of a sinusoidal voltage. In the first and third quarter of the period, the energy is stored in the magnetic field of the inductor, but in the 2nd and 4th quarter of the period, the energy is released from the inductor to the rest of the circuit.
