When is maximum energy stored in an inductor?

Maximum energy is stored in an inductor when maximum current density in the winding and maximum flux density in the core occur simultaneously. Maximum current in the winding is always a thermal loss limitation, while core flux may be either loss or saturation limited.

Can inductor design achieve high Q at high power and high frequency?

Simulations of an example inductor support that the modi ed dumbbell geometry and guidelines can achieve high Q at high power and high frequency. The developed design techniques and proposed inductor structures are therefore suitable for achieving low-loss HF inductor designs for a potentially wide range of applications.

How do you calculate the stored energy of an inductor?

n be determined by the following calculation: I ductors should ore energy. The stored energy of an inductor is: W = LI 2. This energy isstored as magnetic ield energy, within the ferrite core and within the air gap (see Fig.5.1 1). The higher the required stored the energy the larger the required core

Can high frequency inductors miniaturize power electronics?

Operation in the high frequency (HF) regime (3{ 30 MHz) has potential for miniaturizing power electronics, but designing small, e cient inductors at HF can be challenging. At these frequencies, losses due to skin and proximity e ects are di cult to reduce, and gaps needed to keep B elds low in the core add fringing eld loss.

How can HF inductor design be improved?

This thesis aims to improve the design of HF inductors. A low-loss inductor structure for HF applications and associated design guidelines that optimize for loss have been developed. The structure achieves low loss through quasi-distributed gaps and a new eld shaping technique that achieves low winding loss through double-sided conduction.
