Which passive element stores energy?

Unlike resistors, which dissipate energy, capacitors and inductors store energy. Thus, these passive elements are called storage elements. A capacitor stores energy in its electric field. A capacitor is typically constructed as shown in Figure 5.1.

What is the difference between a resistor and a storage element?

Electric and magnetic fields are duals of each other, differ from resistors in several significant ways. Unlike resistors, which dissipate energy, capacitors and inductors do not dissipate but store energy, which can be retrieved at a later time. They are called storage elements. Furthermore, their branch variables do not depend algebraically

Do storage elements depend on each other?

but store energy, which can be retrieved at a later time. They are called storage elements. Furthermore, their branch variables do not depend algebraically upon each other. Rather, their relations involve temporal derivatives and integrals. Thus, the analysis of circuits containing capacitors and inductors involves differential equations in time.

Second Order Circuits Second order circuits have 2 independent energy storage elements (inductors and/or capacitors). Analysis of a 2nd-order circuit yields a 2nd-order differential equation (DE). A 2nd-order differential equation has the form: $\frac{d^2x}{dt^2} + \dots = 0$. Solution of a 2nd-order differential equation requires two initial conditions: $x(0)$ and $\frac{dx}{dt}(0)$.

Instead of analysing each passive element separately, we can combine all three together into a series RLC circuit. The analysis of a series RLC circuit is the same as that for the dual series RL and RC circuits we looked at previously, except ...

Modulated Energy Storage is Prohibited Previously we encountered the use of modulated power sources to describe how a control system might influence the energy supplied to or removed from a system. When we consider energy-storage elements, an important restriction must be emphasized: modulation of energy storage elements is prohibited.

The system of Fig. 6.5 contains both energy storage and energy dissipation elements. Kinetic energy is stored in the form of the velocity of the mass. The sliding coefficient of friction dissipates energy. Thus, the system has a single energy storage element (the mass) and a single energy dissipation element (the sliding friction). In section 4 ...

The energy storage inductor in a buck regulator functions as both an energy conversion element and as an output ripple filter. This double duty often saves the cost of an additional output filter, but it complicates the process of finding a good compromise for the value of the inductor.
