What is thermal runaway in a battery?

Thermal runaway in a battery is a chain reaction that leads to rapid temperature and pressure increase. This reaction starts when the battery's internal temperature reaches a point that causes a breakdown of the internal components. It can escalate quickly, potentially leading to a fire or explosion.

What is thermal runaway?

Thermal runaway is one of the primary risks related to lithium-ion batteries. It is a phenomenon in which the lithium-ion cell enters an uncontrollable, self-heating state.

What can cause thermal runaway in lithium-ion batteries?

Thermal runaway in lithium-ion batteries can be caused by uncontrolled thermal conditions. This phenomenon occurs when a battery becomes self-destructive, leading to potential hazards.

Why is understanding thermal runaway important?

Understanding and mitigating thermal runaway is vital for the safe utilization of lithium-ion batteries. Through continuous research, technological advancements, and adherence to safety standards, the risks associated with thermal runaway can be significantly reduced, paving the way for safer and more reliable battery technology.

What is the trigger temperature for thermal runaway?

Identifying the trigger temperature for thermal runaway in lithium-ion batteries is complex, as it varies based on battery composition and design. Generally, thermal runaway becomes a significant risk at temperatures above 80°C (176°F). Once this threshold is crossed, the risk of chemical reactions leading to thermal runaway increases significantly.

What is the most common cause of thermal runaway?

The causes of thermal runaway in lithium-ion batteries are diverse and often interrelated. Here's a more in-depth look: The most common cause is internal short circuits, which occur due to physical damage, manufacturing defects, or the breakdown of internal separators.
