What is a high-pressure gaseous storage system?

How does electricity storage work?

The electric energy produced is then fed into the electricity network using a transformer. A unique characteristic of this electricity storage system is that it uses rock to store potential energy at a density many times higher than the energy density of water. This results in higher storage capacities.

Another theoretical mechanical stored energy concept is called the gravity power storage system. Unlike the hydraulic rock storage system described in Abschn. 9.3.2.1, the dimensions of the gravity power system are small. The storage principle is also slightly different, since it uses the same principle as the power tower system (Abschn. 9.3.2.3).

How does a compressed air energy storage system work?

The utilization of the potential energy stored in the pressurization of a compressible fluid is at the heart of the compressed-air energy storage (CAES) systems. The mode of operation for installations employing this principle is quite simple.

Conversely, as the pressure on a gas decreases, the gas volume increases because the gas particles can now move farther apart. Weather balloons get larger as they rise through the atmosphere to regions of lower pressure ...

If the gas is ideal (ie:  $PV = mRT$ ) then the expansion (increase in  $V$ ) will exactly counter the pressure drop (decrease in  $P$ ) to give you a constant (ie:  $PV = \text{constant}$  for ideal gas). In the case of a real gas, this isn't always the case. Under typical circumstances,  $PV$  is slightly lower after the expansion, so the gas is very

1) The gas decreases to a lower pressure. 2) The gas will increase in volume. 3) Enthalpy will stay the same (one caveat regards overall fluid velocity, but for your typical fluid system, this contribution to enthalpy can be neglected). Enthalpy is:  $H = U + PdV$  Where  $H$  = enthalpy  $U$  = internal energy  $PdV$  is a pressure energy term.

I don't think what i've written disagrees with you, does it? The point here is that the ideal gas law doesn't model the internals of the non ideal gas that lead to a heat capacity. It's the "fudge" of adding a heat capacity and the modelling of heat storage in these internals that gives rise to the different constant  $R$  and the adiabatic ...
